

Cross-cuttingness, Cleavage Structures and Civil War Onset

JOEL SAWAT SELWAY*

This paper seeks to further our understanding concerning the effect of social structure on civil war onset. Studies to date have been inconclusive, focusing only on single-cleavage characteristics of social structure, such as ethnic or religious fractionalization. This study argues that models that ignore the relationship between cleavages (or cleavage structure) are biased and thus reach faulty conclusions. Focusing on the cleavages of ethnicity and religion, I define and test the effect of two characteristics of cleavage structure on civil war onset: cross-cuttingness and cross-fragmentation. Using a new index of ethno-religious cross-cuttingness (ERC) derived from national public opinion surveys, I find that ERC is a significant determinant of civil war onset when interacted with ethnic fractionalization.

The author wishes to thank Rob Franzese, Ashutosh Varshney, Allen Hicken, Ken Kollman, Joshua Gubler, and various participants in the World Politics Internal Seminar at the University of Michigan (December 2007) for their advice and comments. Thanks also to Ronald Inglehart, James Fearon and David Laitin, and Henrik Urdal for sharing their data; and to the anonymous reviewers and the Editors of the *Journal* for their helpful suggestions.

Keywords: Civil war, ethnic fractionalization, social structure, ethnic conflict, cross-cutting cleavages, cross-cuttingness

INTRODUCTION

The Sri Lankan civil war, which began on 23 July 1983 when the Liberation Tigers of Tamil Eelam (LTTE) killed 13 members of the Sinhalese-dominated government forces, is one of the deadliest ongoing armed conflicts in the world. Over 70,000 lives have been claimed in this 26-year conflict, which seems to be escalating: an estimated 9,000 were killed on both sides over the last two years alone.¹ Meanwhile, to Sri Lanka's north, India's *mélange* of ethnic groups have avoided serious armed conflict over the sixty-odd years since the country's independence. With over nineteen ethno-linguistic groups with populations over 10 million in India, the wealth of civil war literature on the danger that ethnic fractionalization poses for a country's stability would predict just the opposite for these two countries. How can we explain this puzzle?

There has been increasing interest over the past decade concerning the effect a country's social structure has on the risk of civil war onset. These studies have focused on a variety of social cleavages, including socio-economic class, ethnicity and religion, positing that certain characteristics of these cleavages (e.g. fractionalization and polarization) make societies more likely to engage in civil war.² A long-recognized shortcoming of such models, however, is how to handle the inclusion of two (or more) cleavages. Specifically, two significant challenges relate to this multiple-cleavage issue: the first and most important is capturing how multiple cleavages relate to each other, or what Lipset terms the overall structure of a society's salient cleavages;³ the second, is how we should include social structure characteristics in civil war models – additively, as they have been thus far, or multiplicatively? As such, this paper seeks to contribute to the conceptualization, measurement and empirical testing of cleavage structures in relation to civil war. Notably, I return to the characteristic of *cross-cuttingness*, which received much

theoretical attention in the pioneering work of Lipset and others in the 1960s and 70s, and introduce the first cross-country index of ethno-religious cross-cuttingness.⁴

Indeed, it is cross-cuttingness that answers the Sri Lanka-India question posed at the outset: because religion reinforces ethnicity in Sri Lanka the divisibility and bargainability of conflictual issues is hopelessly diminished. In contrast, religion cross-cuts ethnicity in India and has helped moderate potentially divisive issues, making possible such compromises as regional autonomy for certain ethnic groups.⁵

In this paper, I argue that ethno-religious cross-cuttingness makes civil war less likely because it reduces the saliency of out-group differences and thus makes it harder for potential rebel leaders to recruit based on ethnic appeals. The major empirical finding of this paper is that cross-cuttingness is a significant determinant, both substantively and statistically, of civil war onset conditional on ethnic fractionalization. Specifically, the marginal effect of cross-cuttingness on civil war onset is negative and significant at low levels of ethnic fractionalization. This result is robust to the numerous sources of civil war onset data and the numerous indices of ethnic fractionalization and bipolarization. Thus, our understanding of the role ethnicity plays in civil war onset is inaccurate unless we take into account the modifying effect of cross-cutting cleavages.

The paper proceeds as follows. First, I review the state of knowledge relating social structure to civil war onset, highlighting several areas where innovation is needed. Second, I present the logic linking cross-cuttingness to civil war. I then proceed to define cross-cuttingness, discussing various ways it has been conceptualized and measured in the literature. Next, I describe the new index and proceed to test the influence of cross-cuttingness on civil war onset. The final section concludes with a discussion on future innovation in the area of social structure and civil war.

SOCIAL STRUCTURE AND CIVIL WAR

The civil war literature is immense, and many diverse determinants of civil war onset have been postulated and empirically evaluated. It is not my intention to review this literature in its entirety; rather, I emphasize two major strands: motivation and feasibility.⁶ The motivation literature has examined the reasons that rebel groups choose to engage in armed conflict, focusing on greed vs. grievance as triggering factors.⁷ In the second strand, feasibility, falls work such as Fearon and Laitin's⁸ study on favourable geographic conditions for insurgency and Urdal's⁹ study on youth bulges – the idea being that geography and demographics, respectively, lower the cost of financing rebel military forces. Social structure theory incorporates elements of both these strands: in terms of motivation, while it is irrelevant *what* the precise stimulus of the civil war is, certain societal arrangements increase the likelihood that *some* kind of spark will ignite into armed conflict.

With regards to feasibility, social structure theory posits that certain kinds of structures lower the costs associated with civil war. For example, recent work by Cederman et al. argues that the geographic distribution of ethnic groups makes it easier for potential rebels to recruit militants.¹⁰ The logic is two-fold: first, when ethnic groups are concentrated in a geographic region, transportation costs of recruitment decline. Second, geographic concentration of ethnic groups strengthens in-group loyalties by forming ethno-regional identities, which are crucial to the emergence of proto-nations.

I argue in this paper that the structure of two salient cleavages in society – ethnicity and religion – affects both the likelihood that disagreements are interpreted in less bargainable and divisible ascriptive group terms (motivation) and the costs for potential rebels to recruit combatants (feasibility). The motivational part of my

argument captures something about the diversity, or harmony, of societal preferences concerning various social, political and economic issues. For example, we might expect a society with many different linguistic groups to be more divided over education policy, perhaps because each linguistic group will demand instruction in its own language. Or take the distribution of bureaucratic jobs; we might expect two large, evenly-sized ethnic groups to fight for dominance of the share of jobs and perhaps the working language of government (this is, in fact, a frequent problem in the developing world). In short, group loyalty is associated with different preferences on issues, especially resource distribution or policy implementation.

The strength of group loyalty – a group’s sense of self, its organizational capacities, or the loyalty of its members – also affects the feasibility aspect of my argument.¹¹ In the same way that greater association of geographic region with ethnicity strengthens group loyalty, greater association between religious affiliation and ethnicity also leads to more solidified group loyalties. In turn, the costs of recruiting rebels are lowered. First, because in a sense individuals now have two reasons to mistrust members of society who do not share either ethnic or religious identity, rebels do not need to expend as many resources convincing disaffected members of their in-group to join their cause. When a social group has a clearly defined sense of self its members share *common knowledge* that make interaction with, and understanding of fellow members easier.¹² Religious and ethnic affiliation also provides ready-made social networks that make recruitment easier.¹³

Before proceeding, let me respond briefly to a common critique of work that looks at social structure (the work on ethnic fractionalization has been the favourite whipping boy) and civil war, which is as follows: If group-based grievances underlie civil wars, why not employ a more direct measure of how aggrieved ethnic groups are? Indeed, recent work has suggested that “the key factor driving this struggle over

state resources is political discrimination orchestrated by powerful state actors”.¹⁴ Cederman and Girardin’s exemplary work creates an aggregate measure of ethnic political discrimination for each state in the sample.¹⁵ Such innovations are to be commended and, rather than invalidating social structure theory, which tends toward the “grand” end of the levels of theory spectrum, this literature on ethnic exclusion has more specifically tested the motivational mechanism that underlies social structure theory. The problem with conflating this work with tests of social structure theories is two-fold. First, political discrimination only captures expressed instances of group-based grievances. It thus cannot answer the question of which arrangements of social groups most reduces the likelihood of the onset of civil war. Furthermore, political discrimination is essentially one part of broader inter-group conflict of which violence and civil war constitute other elements. Thus, there is a possible endogeneity problem with using a measure of political discrimination.

Instead, I advocate the use of general social structure data to examine ethnic and religious causes of conflict. Specifically, these measures capture the *potential* for all types of inter-group conflict, including political discrimination and political violence. Certainly, political discrimination may be one possible intervening variable, but primordialists would argue that ethnic groups fight out of some inherent dislike for each other unrelated to actual grievances. Lastly, civil wars can ignite in very short periods of time. Prolonged prior grievances, such as political discrimination, are not a necessary precondition for an outbreak. Thus, social structure measures, as gauges of potential conflict of all types and intensities, better capture the relevant social dynamics.

Three questions regarding social structure have occupied the literature in relation to civil war onset: Which cleavages, which groups, and which characteristics? The first question has captured the most attention. Whilst numerous scholars have

argued that a country's social structure¹⁶ makes conflict more likely, they have not agreed on which *cleavages*¹⁷ matter. For example, Horowitz argues convincingly that the ethnic cleavage is chief amongst the underlying determinants of civil war.¹⁸ Fox provides a similar compendium to Horowitz with regard to the relationship between religion and civil war.¹⁹ Collier and Hoeffler²⁰ have consistently argued that socio-economic class, in the form of inequality measures, explains civil war.²¹ Lastly, Cederman²² argues that geo-cultural identity is related to the likelihood of nationalist insurgency.²³

This study focuses on ethnicity and religion.²⁴ Rae and Taylor argue that ethnicity and religion are *ascriptive*, i.e. individuals are born with these identities, or memberships, which are then difficult, if not impossible, to change or to hide.²⁵ Due to their permanent nature, ascriptive cleavages make bargaining over issues difficult. One needs only to think of the Israeli-Palestinian situation to see how immovable policy positions are in an ethno-religiously split nation. Indeed, as we scan the world, in almost every society we find countless examples of ethnic or religious conflict.²⁶ Thus, scholars have focused on characteristics of ethnicity and religion assuming that the ascriptive nature of these two cleavages makes their salience likely (though not certain) to be high in most societies.²⁷ In contrast, groups along the socio-economic cleavage are likely to find it much harder to overcome the collective action problem. In addition, distributional debates, which will be the issue at the heart of disputes along the socio-economic cleavage, are much easier to solve since the bargaining space is continuous.

In addition to which cleavage matters, fruitful discussion has taken place on which *groups* within cleavages matter.²⁸ Should we be concerned only about relevant/politicized groups²⁹, or are we trying to capture the latent potential³⁰ for conflict? Posner, in his study of economic development in Africa, argues for the

inclusion of only those ethnic groups that “participate in politics as distinct, recognizable groups” engaging in “interethnic competition on economic policymaking”.³¹ The claim is not that Posner’s revised fractionalization index is appropriate for all studies, but that the inclusion of groups should reflect the explicit mechanism the researcher is trying to test. For the current study, I thus favour the use of all potential groups with which individuals can identify. The logic is that counting only politically relevant groups seems to introduce something of an endogeneity problem in the case of civil war onset. Specifically, if relevant groups are chosen because of their political involvement, where involvement may include political violence there is danger of circular logic. Furthermore, which groups would the researcher select in countries that have experienced no civil war?

Finally, once we have decided which cleavages and groups matter, there is the issue of which *characteristics* of these cleavages matter. These characteristics and terms are not used consistently throughout the literature and thus a brief clarification is in order.³² *Fractionalization* (or fragmentation) of either the religious or ethnic cleavages is the most common characteristic used in civil war literature.³³ This measures the number of groups on a cleavage weighted by their size -- the effective number of groups. More recently, Reynal-Querol introduces a measure of *bipolarization* (the extent a cleavage is characterized by two groups of equal size), again along the ethnic and religious cleavages.³⁴ A number of other characteristics have been suggested and tested, including size of the largest group, size of largest minority group, and percent of population not speaking the official language.³⁵ All these measures are uni-dimensional, that is, they describe a single cleavage. To date, little work has been done on multi-dimensional, or multi-cleavage, characteristics.

Empirical studies have diverged greatly regarding which characteristics affect the likelihood of social conflict, and even what the direction of that characteristic’s

relationship with civil war is. Moreover, a focus on different characteristics produces different theoretical stories. Scholars who have used ethnic fractionalization argue that the multiplicity of diverging preferences in society leads to a higher risk of conflict. Others who have looked at bipolarization insist that two large groups of equal size makes conflict more likely because preferences are more intense, less divisible, and less bargainable. Currently, we have little sense of which theoretical arguments are empirically most supported.

Collier and Hoeffler find that social fractionalization is negatively related to civil war onset.³⁶ Their index is statistically significant, but has a small substantive effect. Fearon and Laitin, in contrast, find both ethnic and religious fractionalization to be positively related to civil war onset, but not significantly so.³⁷ Montalvo and Reynal-Querol confirm Fearon and Laitin's findings on ethnic and religious fractionalization being statistically insignificant (though the latter is negatively related).³⁸ However, the authors find that ethnic and religious bipolarization are positively related to civil war onset with their coefficients being substantively and statistically significant. Hegre and Sambanis, attempting to sort out these empirical inconsistencies, perform sensitivity analysis and find that variables representing ethnic difference in the population are robust only in relation to lower-level armed conflict.³⁹ However, Quinn, Hechter and Wibbels use a Bayesian approach and conclude that once measurement error is taken into account, ethnic diversity turns out to have a significant effect on civil war onset at high levels of armed conflict.⁴⁰ In sum, previous studies exploring the link between social structure and civil war have been inconclusive regarding both the direction and statistical significance of various characteristics.

To the author's knowledge only one attempt has been made to deal with multiple cleavages other than summarily including them in an additive model. Collier

and Hoeffler offer a measure of social fractionalization, to handle multiple cleavages in the absence of a true measure of cross-cuttingness.⁴¹ The Collier and Hoeffler social fractionalization measure takes the product of the separate religious and ethnic fractionalization indices plus the higher of the two. This, they say, captures the maximum potential for social fractionalization. They do not find strong evidence for its inclusion in civil war models, however.

CROSS-CUTTINGNESS AND OTHER CLEAVAGE-STRUCTURE CHARACTERISTICS

One reason for the inconsistency of findings relating single-cleavage characteristics to civil war is that a major piece of information is missing that relates them to the underlying mechanisms: *how* one characteristic is structured in relation to other salient cleavages. Specifically, in this paper I investigate how ethnic identity is structured in relation to religious identity (and vice-versa). Whether one chooses to draw on the preferences, collective action, or in-group altruism logic, fractionalization (or bipolarization) alone fails to capture the underlying mechanisms relating social structure to civil war. Consider two societies with identical levels of religious and ethnic fractionalization and bipolarization. For illustrative purposes, consider two societies with two ethnic groups and two religious groups of equal size. In the first society, ethnic group *a* belongs entirely to religion *j*, and ethnic group *b* belongs entirely to religion *k*. In contrast, in the second society, both ethnic groups are equally divided among the two religions. Looking solely at fractionalization or bipolarization measures, we would mistakenly conclude that both societies have equal potential for conflict. This is incorrect because the second society is more likely to have similar preferences between its two groups due to them belonging to the same religion. In contrast, in the first society, preferences become more polarized between ethnic groups due to the religious split.

The roots of cross-cutting theory can be attributed to German sociologist George Simmel, who in his 1908 *Soziologie* postulated relationships between a number of characteristics of macro social structure and various aspects of social life.⁴² Specifically, Simmel argued that cross-cutting social circles led to higher levels of individualization. Greater individualization, in turn means lower in-group altruism, which is key in breaking down boundaries and building bridges amongst social groups, thus reducing the potential for conflict. Sociologists further developed Simmel's idea of cross-cuttingness, with Peter Blau spearheading its development into the sub-field of Macro-Sociology. Blau writes that cross-cuttingness can be thought of as maximizing diversity of memberships across cleavages.⁴³ As the diversity of memberships increases, "group boundaries [become] more permeable, status distinctions more easily bridged, and intergroup relations more frequent".⁴⁴ Group boundaries are most permeable when knowing one's group membership on one cleavage tells you nothing about her membership on another cleavage. Blau measures cross-cuttingness with a chi-square measure of independence. I refer to this conceptualization of cross-cuttingness as *pure cross-cuttingness*, which I will define and measure in more detail below.

The field of anthropology should take the "credit for having [first] brought to light [cross-cuttingness'] full significance for the study of social organization" writes sociologist A. Beteille.⁴⁵ However, the anthropological definition of cross-cuttingness differed from the sociological one in important ways. Beginning with Evans-Pritchard, social anthropologists sought to understand how societies, lacking the institution of government, nevertheless maintained an ordered existence.⁴⁶ Gluckman's interpretation of these ethnographies emphasized *conflict of loyalties* as the key to these societies' stability: because an individual's loyalty was split in a cross-cutting society, his or her commitment to any one group was mitigated.⁴⁷ For

example, take Kroeber's description of the Zūni society: "The clans, the fraternities, the priesthoods, the kivas . . . if they coincided, the rifts in the social structure would be deep; by countering each other, they cause segmentation which produces an almost marvellous complexity, but can never break the national entity apart."⁴⁸ This cross-cutting pattern of social structure segmented society into multiple sub-groups, each with a complex web of pressures from each salient social dimension.

Though anthropologists did not seek to quantify cross-cuttingness, their use of the term seems to capture concepts different than *pure cross-cuttingness*, or statistical independence. Specifically, an increase in either the number of salient cleavages or the number of groups within cleavages can multiply the number of sub-groups. We might want to isolate the first concept, an increase in the number of salient cleavages, and refer to it as a distinctive characteristic, say *heterogeneity*. Alternatively, we could take a fractionalization measure of sub-groups to capture the second concept. Thus, we see that anthropology's theoretical focus, operating at a different level of analysis, led to two different concepts, which in fact are quite different from pure cross-cuttingness.

Within political science, an even greater variety of concepts have masqueraded under the term cross-cuttingness. In addition to pure cross-cuttingness, heterogeneity and sub-group fractionalization, two additional concepts can be identified with the appellation cross-cuttingness. Cross-cutting theory enjoyed widespread scholarly popularity in the 1950s and 1960s, and political scientists applied the notion to studies on social order, political violence, voting behaviour, political organization and democratic stability. Truman's work on democratic stability, for example, focused on compromise within the group.⁴⁹ His group cohesion theory argued that the "influence of the affected group depend[s] upon the conflicting loyalties of any significant segment of the group." One implication of group

cohesion theory is that the more fragmented a group is on a second cleavage, the less hold it has on its members, i.e. the lower in-group altruism. This version of cross-cuttingness seems to be best captured by *cross-fragmentation*, a concept formalized by Rae and Taylor.⁵⁰ Elsewhere in the democratic stability literature, Lipset argues that: “A system in which the support of different parties corresponds too closely to basic social division cannot continue on a democratic basis.”⁵¹ This concept of cross-cuttingness is most similar to sociology’s *pure cross-cuttingness*.

The voting literature and its focus on the individual, however, alluded to yet a different concept – *heterogeneity*. When deciding for whom to vote, membership in different groups with different political opinions was said to pull an individual in different political directions. “More memberships,” is another way to say that more salient cleavages exist in a given society. Lastly, Dahl reasoned: “If most individuals in the society identify with more than one group, then there is some positive probability that any majority contains individuals who identify for certain purposes with the threatened minority.”⁵² This probability is maximized when all groups on all cleavages are proportional in size and when any given group is evenly split amongst groups on a second cleavage. Selway refers to this definition of cross-cuttingness as *cross-proportionality*.⁵³

In general, then, the term cross-cuttingness has been used to refer to a variety of characteristics describing the *structure of cleavages* in society. These cleavage-structure characteristics differed depending on the motivating level of analysis of the question. Thus, at the individual level, the focus is on the competing identities and/or associations of an individual with multiple group affiliations. The more identities an individual possesses, the more he or she feels *cross-pressured* from these different groups, so the logic goes. Rae and Taylor’s *cross-fragmentation* measure was motivated by this first dynamic of individual cross-pressures, deriving their measure

from the premising question: what is the probability two individuals belong to the same group on one cleavage, but different groups on another cleavage?⁵⁴ In contrast, Blau’s conceptualization and measure of cleavage-structure was motivated by dynamics at the cleavage level.⁵⁵ Specifically, he wondered how “lines of differentiation (cleavages) [were] related to one another”, and the “strength of the relationship of two or more social differences”.⁵⁶ This led Blau to conceptualize the structure of cleavages in terms of how independent each salient cleavage is from the other. Lipset also seemed to operate at the cleavage level as he focused on the fluidity of issue coalitions. When cleavages are highly related (reinforcing society), Lipset sees less flexibility in coalitions. The same coalitions appear over and over again on every issue. In contrast, when cleavages are highly independent, different coalitions are possible for each issue that arises; the *us*’s and the *them*’s are constantly changing.⁵⁷ In the remainder of this section, then, I define and measure these two major characteristics of cleavage-structure more precisely, testing them both in the empirical section.

CROSS-FRAGMENTATION

Cross-fragmentation, whose formal definition can be attributed to Rae and Taylor⁵⁸, measures the proportion of all pairs of individuals who are in the same group on one cleavage but in different groups on another cleavage. It is given by the equation:

$$CF = \frac{\frac{1}{2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} x_{ij} (x_{i\cdot} - x_{ij}) + \frac{1}{2} \sum_{i=1}^{n_2} \sum_{j=1}^{n_1} x_{ij} (x_{\cdot j} - x_{ij})}{N(N-1)/2}, \quad (1)$$

where x_{ij} are frequencies in the cells of a contingency table of the two cleavages i and j , $x_{i\cdot}$ and $x_{\cdot j}$ are the marginal frequencies and N is the total number of individuals in the society. If N is large enough for the approximation $1/N(N-1) \approx 1/N^2$ to hold, then Rae and Taylor show that this can be written

$$CF = \sum_i p_{i\cdot}^2 + \sum_j p_{\cdot j}^2 + \sum_{i,j} p_{ij}^2 \quad (2)$$

which after some transformation is simply:

$$CF = 2F_c - F_1 - F_2 \quad (3)$$

or two times the sub-group fractionalization minus the fractionalization scores for each of the individual cleavages (using the familiar Herfindahl measure of fractionalization in footnote 7). Like F , CF varies between 0 and 1, with 0 signifying complete reinforcingness and 1 complete cross-fragmentation. At the maximum, complete cross-fragmentation occurs when all *pairs* belonging to the same group on i belong to different groups on j , and vice-versa. Put differently, every member of any given group would have to belong to his or her own group on a second cleavage. While this maximum may appear absurd, more practically we can think of cross-fragmentation increasing “the smaller the number of persons who are in the same group in both cleavages.”

PURE CROSS-CUTTINGNESS

Other scholars have used a measure that I refer to as *pure cross-cuttingness*, which seems to isolate a single, distinct characteristic: the extent to which members of

different groups on i belong to the same j groups (and vice-versa). In other words, in answer to the question, “In what way should groups on a cleavage i be distributed amongst groups on a second cleavage j to maximize cross-cuttingness?” pure cross-cuttingness says “when groups are distributed *identically*”. That is, *given* the number of groups and *given* their relative size, cross-cuttingness is maximized when groups are identically distributed among groups on a second cleavage. To the statistically conversant, this seems awfully like the concept of statistical independence, which it indeed is. To make C comparable regardless of the number of groups, I use the normalization of the chi-square statistic given by Cramer.⁵⁹

$$C = I \cdot \sqrt{\left[\sum_{i=1}^k \frac{(O - E)^2}{E} \right] / N \times \max\{(c - 1), (r - 1)\}} \quad (4)$$

Where $\left[\sum_{i=1}^k \frac{(O - E)^2}{E} \right]$ is the chi-square statistic of independence⁶⁰, N is the number of observations, and the term $\max\{(c - 1), (r - 1)\}$ is the larger of either the number of columns (c) minus one or the number of rows (r) minus one. Pure cross-cutting is maximized when knowing the group affiliation of an individual on one cleavage tells you nothing about what his/her group affiliation is on a second cleavage.

To get a further sense of how cross-fragmentation and pure cross-cuttingness diverge, consider the situation where two ethnic groups are each split amongst two religions, but no member of either ethnic group shares a single religious group with a member of the other ethnic group as in Table 1. Cross-fragmentation will have a positive value (0.15) signifying that groups have less hold on their members. In the same scenario, C gives a value of zero signifying that even though ethnic groups are divided religiously, they still identify with and/or associate with members of their

ethnic group. Despite this difference, both measures are sensitive to sub-group identities and thus fulfil Selway's cross-cutting axiom of *Subgroup Identity Sensitivity*.⁶¹

TABLE 1 ABOUT HERE

Cross-fragmentation should still not be confused with cross-cuttingness. While the measure is sensitive to independence between cleavages, cross-fragmentation is also sensitive to fractionalization of either of the cleavages; pure cross-cuttingness is not sensitive to the latter. Cross-fragmentation is perhaps best described as simultaneously capturing cross-cuttingness and fractionalization. Indeed, as the empirical data below show, cross-fragmentation is a completely separate cleavage-structure characteristic from cross-cuttingness.

PURE CROSS-CUTTINGNESS, CROSS-FRAGMENTATION AND CIVIL WAR

The implications of pure cross-cuttingness and cross-fragmentation for conflict and civil war are as follows. Higher levels of either cross-fragmentation and pure cross-cuttingness are theorized to be associated with lower levels of conflict. The risk of conflict, however, is very different from the commencement of (or deterioration into) a civil war. Many other characteristics must be controlled for, including level of economic development and conditions making insurgency more likely (geographic terrain, non-contiguous state, etc.). Nevertheless, once these other factors are controlled for, higher levels of cross-cuttingness and cross-fragmentation should decrease the likelihood of civil war onset.

Hypothesis 1. Higher levels of cross-cuttingness decrease the likelihood of civil war.

Hypothesis 2. Higher levels of cross-fragmentation decrease the likelihood of civil war.

An important issue that accompanies the introduction of pure cross-cuttingness and cross-fragmentation is how they should be entered into our empirical model with single-cleavage characteristics of social structure, i.e. ethnic and religious fractionalization and bipolarization. The choice between additive and multiplicative models is in question here. I posit that the effects of cross-cuttingness and cross-fragmentation are *modified* by single-cleavage characteristics (and vice-versa). In other words, an interactive model is most appropriate.⁶² Ultimately, this is can be viewed as an empirical question, but I now present some theoretical support for such a specification.

One theory states that more ethnic groups entail more preferences in society, and thus more likelihood of disagreement and conflict. Cross-cuttingness theory, however, argues that these differences become less significant in a highly cross-cutting society. For illustrative purposes, consider two societies with two ethnic groups and two religious groups of equal size. In the first society, ethnic group *a* belongs entirely to religion *j*, and ethnic group *b* belongs entirely to religion *k*. In contrast, in the second society, both ethnic groups are equally divided among the two religions. If it is the multiplicity of groups that matters, then one possible line of argument might be that the second society has effectively one group due to the cross-cutting of cleavages. Indeed, as the level of cross-cuttingness increases, the effect of the number of social groups, whether captured by fractionalization or bipolarization, should decrease. This line of reasoning generates the following hypothesis:

Hypothesis 3. Higher levels of ethnic fractionalization increase the likelihood of civil war. This effect decreases as cross-cuttingness (3.1) or cross-fragmentation (3.2) increase.

The same logic can be applied to the common theory that higher levels of bipolarization make conflict more likely. Again, consider two societies with two ethnic groups and two religious groups of equal size. They both have the maximum levels of bipolarization. However, in a perfectly cross-cutting society there would effectively be one group, or effectively zero bipolarization. Thus, we get:

Hypothesis 4. Higher levels of ethnic bipolarization increase the likelihood of civil war. This effect decreases as cross-cuttingness (4.1) or cross-fragmentation (4.2) increase.

In addition, we can add two more similar hypotheses for the religious cleavage:

Hypothesis 5. Higher levels of religious fractionalization increase the likelihood of civil war. This effect decreases as cross-cuttingness (5.1) or cross-fragmentation (5.2) increase.

Hypothesis 6. Higher levels of religious bipolarization increase the likelihood of civil war. This effect decreases as cross-cuttingness (6.1) or cross-fragmentation (6.2) increase.

Hypotheses 3-6 can be tested using the relevant version of the interaction model:

$$\text{Logit of Pr Civil War} = \beta_0 + \beta_1 \text{EthFrag} + \beta_2 \text{CrossCut} + \beta_3 \text{EthFrag} \times \text{CrossCut} + \beta_i \mathbf{X} + \varepsilon,$$

replacing *Ethfrag* with the respective single-dimension variable and swapping *CrossFrag* in for *CrossCut*.

The marginal effect of the single-dimension variables is:

$$\frac{\partial \text{CivilWar}}{\partial \text{EthFrag}} = \beta_1 + \beta_3 \text{CrossCut},$$

again replacing *EthFrag* and *CrossCut*, as each hypothesis calls for. This effect (identical for all single-dimension characteristics) should be positive and significant when cross-cuttingness is sufficiently low. β_1 should be positive because the effect of ethnic fractionalization on civil war is expected to be increasing when cleavages are perfectly reinforcing. Assuming β_1 is positive, β_3 should be negative because the marginal effect of ethnic fractionalization is expected to be decreasing as the structure of cleavages becomes more cross-cutting (less reinforcing). It is helpful to think of cross-cuttingness *modifying* the effect of fractionalization or bipolarization on civil war. In this theory, as cross-cuttingness increases, the effect of fractionalization (bipolarization) on civil war decreases.

Ultimately, I test Hypotheses 3-6 in several models: first, with each single-cleavage characteristic entered separately; and second, in models with various combinations of pairs of single-cleavage characteristics. The most extensive model, then, has 5 variables that attempt to capture social structure, and can be given by the following specification:

$$\begin{aligned} \text{Logit of Pr Civil War} = & \beta_0 + \beta_1 \text{EthFrag} + \beta_2 \text{RelFrag} + \beta_3 \text{CrossCut} + \\ & \beta_4 \text{EthFrag} \times \text{CrossCut} + \beta_5 \text{RelFrag} \times \text{CrossCut} + \beta_i \mathbf{X} + \\ & \varepsilon. \end{aligned}$$

The marginal effect of cross-cuttingness is:

$$\frac{\partial \text{CivilWar}}{\partial \text{CrossCut}} = \beta_3 + \beta_4 \text{EthFrag} + \beta_5 \text{RelFrag},$$

Thus, assuming β_3 is negative, I expect β_4 and β_5 to be positive, i.e. as fractionalization (bipolarization) increases, the marginal effect of cross-cuttingness should decrease. Hence, we get the following hypotheses:

Hypothesis 7: Higher levels of cross-cuttingness decrease the likelihood of civil war.

This effect increases as either ethnic/ religious fractionalization/bipolarization (7.1-7.4) increase.

Hypothesis 8: Higher levels of cross-fragmentation decrease the likelihood of civil

war. This effect increases as either ethnic/religious fractionalization/bipolarization (8.1-8.4) increase.

THE EMPIRICAL RELATIONSHIP BETWEEN MEASURES OF SOCIAL STRUCTURE

In this section, I compare the empirical content of the two-dimensional characteristics of cleavage structure first with each other and second with single-cleavage characteristics. If pure cross-cuttingness and cross-fragmentation are highly related, the differences discussed above would be minor. However, the data reveal that they are indeed distinct characteristics. Moreover, cross-fragmentation, while

being partially derived from both religious and ethnic fractionalization captures something quite different than either the two separate measures. In this section, I describe the data sources for my social structure measures, comparing them to existing indices to ensure a degree of robustness.

The most accurate source for this data would be country censuses. However, many countries do not collect such information, and for those that do the raw data is difficult to obtain. An alternative strategy is to extract similar information from nationally representative surveys, such as public opinion surveys. Accordingly, I compiled my indices from seven sources: The World Values Survey (WVS)⁶³, The Eurobarometer (EB)⁶⁴, the Afrobarometer (AFB)⁶⁵, the Latin American Public Opinion Project (LP)⁶⁶, the Asian Barometer (AB)⁶⁷, the Comparative Study of Electoral Systems (CSES)⁶⁸, and the World Health Organization (WHO)⁶⁹. In addition to the several rounds of WVS, the use of several surveys allowed me to test the robustness of my scores for a handful of countries that appeared on two or more of the surveys. The full data are displayed in Table 1 of the appendix.⁷⁰

I begin my description of the data with a worked example of how the cross-cuttingness score is calculated. I chose Switzerland, since it was the quintessential example of a cross-cutting country in the earlier political science literature cited above. The data come from the World Values Survey round conducted in 1996. Four ethnic groups are picked up by the survey (German 48%, French 31%, Italian 10% and Spanish 1%), as well as an additional category of “Other”, which constitute 2% of the population and likely includes the Romansch people. The survey also picks up 6 religious affiliations plus an “Other” category, the largest two, Catholic and Protestant, constituting 56.4% and 40.6% of the population respectively. Table 2 displays these two cleavages in a cross-tabulation. Out of a total N of 1088

respondents, the largest ethno-religious group is German-Protestants, with 297 individuals, or 27.3% of the population.

TABLES 2 & 3 ABOUT HERE

Table 3 displays the *expected* size of ethno-religious groups if the society were perfectly cross-cutting. This is calculated by taking the product of N and the column and row percentages from Table 2. We thus see that the expected size of German-Protestants is 213.28. The next stage in the process is to subtract the expected values from the observed values. Each of these numbers are then squared and divided by the respective expected values. Due to space limitations, I do not show these stages in tabular form. Taking the sum of the values from the previous stage gives us the chi-square value, which in the case of Switzerland is 381. To normalize this value, I first divide the chi-square value by N (1088) and the lesser of the number of ethnic groups minus one (4) or the number of religious groups minus one (6), as follows.

$$\rightarrow 381 / 1088 \times 4 = .0875$$

Finally, I take the square root of this number and subtract it from unity.

$$\rightarrow 1 - \sqrt{.0875} = .706$$

This produces a final cross-cuttingness score of .706 for Switzerland.

I performed several robustness checks on the indices to ensure the data were reliable. A full description of these checks are available in the appendix, and provide confidence that the methods of survey sampling across the various surveys were

adequately similar and ensured representativeness of the populations.⁷¹ In addition, as I was using several surveys, there were a number of countries that I was able to calculate several scores for. In general, scores were very similar. For example, the average standard deviation for cross-fragmentation was 0.072. Final scores were averaged unless there were theoretical reasons to favour one over the other, such as the tendency to pick up latent cleavages, or worrisome divergence from existing social structure indices.⁷² As such, the measures are fairly consistent across surveys. Finally, I compared ethnic categorizations in the various surveys to Posner's index of Politically Relevant Ethnic Groups (PREG) to ensure that the surveys were picking up latent cleavages, which I argue are appropriate for this study.⁷³

Since I am using this index to study civil war, I was concerned about the geographic spread of the countries for which I was able to compute a score. Moreover, since GDP per capita is at the heart of Fearon and Laitin's theory of state strength, it is important to ensure that the sample of countries I have in my index are representative.⁷⁴ Of the 168 countries with a population over 400,000, the CC and CF indices have scores for 102 countries. 23 of 25 countries in Western Europe, 23 of 27 in Eastern Europe, 17 of 24 in Asia Pacific, 21 of 25 in Latin America, 10 of 22 in the Middle East and North Africa, 18 of 46 in Sub-Saharan Africa.⁷⁵ The average GDP per capita of countries not included in the cross-cutting and cross-fragmentation measures are given in Table 4.

The difference in economic development between in- and out-sample countries is almost \$5,000, meaning that the regression results might be biased away from factors of civil war in poorer countries, which may tend to experience more civil wars than richer countries. However, this disparity in levels of economic development is not seriously pronounced in the region that experiences the most civil wars – Africa. Indeed, in West Africa, out-sample countries actually have a higher

GDP per capita. Nevertheless, this difference in average GDP per capita is certainly something to be aware of when evaluating the results. In general the indices have good regional coverage.

Figure 1 shows a scatter plot of pure cross-cuttingness and cross-fragmentation. Both measures are on a 0-1 scale, though the maximum value of CF is 0.78. While there is a mild positive relationship (0.403 Pearson Correlation), it is clear that for the majority of observations, which lie in the right half of the graph, a country's level of pure cross-cuttingness (CC) does not easily predict its level of cross-fragmentation (CF). That the few observations in the left half of the graph are more strongly correlated supports a theoretical statement I made previously. All measures and conceptualizations of cross-cuttingness in the literature seemed to agree on the definition of the minimum level of cross-cuttingness (reinforcingness); it was the definition of the maximum where divergence took place. Indeed, from a CC value of about 0.5 upwards, CF ranges almost the entire spectrum. Thus, CC and CF are slightly related, but clearly very different characteristics.

FIGURE 1 ABOUT HERE

REGRESSION RESULTS

In this section, I add cross-cuttingness to Fearon and Laitin's⁷⁶ model of civil war. Their model consists of variables measuring state strength and the favourability of a country's geography to insurgency, which they argue is the major method civil war has been waged since the end of WWII. In their study, Fearon and Laitin find no support for religious or ethnic fractionalization determining civil war. The unit of analysis is country year, and each observation is assigned a value of 1 if a civil war began (but not continued) in that year and a 0 otherwise. As such, I use a logit model

to estimate the coefficients. Since the data are Binary Time-Series Cross-Sectional (BTSCS), I follow Beck, Katz and Tucker and employ natural cubic splines to control for temporal dependence between observations.⁷⁷ I also employ robust standard errors clustered by country to control for within-country effects. The sample includes 160 countries and covers the period 1945-1999. In the initial analysis, I use the Peace Research Institute of Oslo (PRIO) dataset for civil wars.⁷⁸ PRIO defines a civil war as a contested incompatibility that concerns government and/or territory, where the use of armed force between two parties, of which at least one is the government of a state, results in at least 25 yearly battle-related deaths and a minimum of 1,000 during the course of the civil war. In the robustness appendix, I test the results using alternative sources of onset data.⁷⁹

Because aspects of social structure could be associated with other things believed to influence civil wars, I control for several variables that affect the cost of rebel groups engaging in armed conflict. First, I control for state strength, captured as follows: the log of per capita income lagged one year (*Income*), the log of the population size lagged one year (*Population*), whether the country experienced a significant change in its political regime in any of the prior three years (*Instability*), and whether the country is in its first or second year of independence (*New State*). The first two of these proxies may also be capturing direct costs for rebel recruitment. In terms of state strength, richer states are better able to finance standing armies, which would both deter and control rebellious activities. Collier and Hoeffler use this same measure, however, to proxy for forgone income – higher per capita income makes it harder for rebel groups to recruit.⁸⁰ Conversely, states with larger populations are inherently weaker, thus increasing the likelihood of civil war. With regards to state strength, larger populations make it harder and more costly for the government to track activities at the local level. However, larger populations also

increase the pool of potential combatants that rebel leaders can draw on. In addition to *Income* and *Population*, the cost of rebel activities is reduced (in this instance in sheer financial terms) if the country has economic activities in primary commodities. Collier and Hoeffler find that oil is the primary commodity that seems to contribute most to rebel financing.⁸¹ Thus, I simply use a dummy for whether a country is an oil exporter (*Oil*).

Next, I control for geographic conditions that make insurgency more likely. Fearon and Laitin persuasively argue that civil wars following WWII have mainly taken the form of insurgency, or rural guerrilla warfare, and offer the two following proxies: the log of the proportion of the country that is mountainous (*Mountains*) and whether the country is non-contiguous, consists of territories separated from the land area containing the capital city (*Noncontiguous*).⁸² The existence of these geographic conditions favourable to insurgency thus reduces the costs of rebel groups engaging in armed conflict.⁸³

For the social structure characteristics I rely initially on all my measures calculated from the surveys mentioned above, namely cross-cuttingness (*CC*), cross-fragmentation (*CF*), ethno-linguistic fractionalization (*SELF*), ethno-linguistic bipolarization (*SELB*), religious fractionalization (*SRF*) and religious bipolarization (*SRB*). In the robustness section, I present my findings using alternative indices of these characteristics.

PURE CROSS-CUTTINGNESS AND THE ONSET OF CIVIL WAR

In Model 1 of Table 5, I replicate Fearon and Laitin's (F&L) model of civil war onset with *PRIOonset* as the dependent variable and my social structure variables for ethnic and religious fractionalization. Similar to what F&L find, the coefficient on religious fractionalization is small and statistically insignificant.⁸⁴ However, as the

several more recent studies that I cite above have shown, we cannot be as certain of F&L's conclusion concerning ethnic fractionalization: using my social-structure data, ethnic fractionalization is significant and positive at $p > .01$. However, substituting back in F&L's original ethnic and religious variables, it again loses significance. The two measures of state strength, log of GDP per capita and the oil dummy are notably both insignificant in Model 1. Changing back to the original F&L onset data for the dependent variable, but with my social structure variables finally finds *Oil* and *Income* significant again. It appears, from this sensitivity analysis, that even the empirical support for state strength determining civil war is shaky.⁸⁵

In Model 2, I add pure cross-cuttingness (CC) as the sole measure of social structure, keeping all other variables the same as in Model 1. The coefficient on CC is negative and significant, both substantively and statistically, as expected. In Model 3, I add ethnic fractionalization (SELF) and religious fractionalization (SRF) back into the model. SRF remains insignificant, while CC and SELF are both significant again. Robustness tests, however, do *not* confirm that either pure-crosscuttingness or ethnic fractionalization are significant in additive models.⁸⁶

TABLE 5 ABOUT HERE

Model 4 includes an interactive term between SELF and CC. The coefficient on CC is negative and significant, indicating the marginal effect of CC on civil war onset is significant when SELF is zero. The interactive term, moreover, is positive, indicating that as SELF increases the effect of CC on war onset increases; the coefficient is also significant. In Model 5, where I interact cross-cuttingness with religion, the coefficient on SRF and the interaction term are not significant. It is important to remember, though, that we are not primarily interested in whether the

coefficient on this interaction term is significant. Instead, what we really want to know is the direction and significance of the *marginal effect* of ethnic fractionalization. Kam and Franzese caution us about conflating coefficients with marginal effects.⁸⁷ Thus, they suggest plotting the marginal effect (taking the partial derivative with respect to the variable of interest) along a reasonable range of values of the variable with which it interacts. Doing so reveals a richer story of how social structure affects civil war. Specifically, I find that the marginal effect of ethnic fractionalization is significant, but only at certain levels of cross-cuttingness.

What we are most interested in, however, is the marginal effect of cross-cuttingness on civil war. Figure 2 (top-left) shows that at certain levels of each of the single-cleavage characteristics, the marginal effect of cross-cuttingness on civil war onset is negative and significant. One can easily observe significance in marginal effects plots: the effect of ethnic fractionalization is significant whenever the upper and lower bounds of the confidence interval are both either above or below the 0 line. Figure 2 (top-left) shows that when fractionalization is low (less than 0.4) the effect of cross-cuttingness on civil war is significantly negative. Put differently, when there are effectively two ethnic groups or less in a society, the effect of cross-cuttingness on civil war is significantly negative.

FIGURE 2 ABOUT HERE

Thus, cross-cuttingness really matters in societies composed of a large ethnic group and a small minority. However, when there are effectively more than two ethnic groups, cross-cuttingness does not have a significant reductive effect on the likelihood of civil war onset. The positive slope also suggests that as ethnic fractionalization increases, the reductive effect of cross-cuttingness on civil war

weakens. Thus, CC matters more the smaller the minority. This is contrary to Hypothesis 7.1, but nevertheless intuitive. For the other three single-cleavage characteristics (ethnic and religious bipolarization and religious fractionalization) the marginal effect of cross-cuttingness is negative and significant at medium values, as shown in the remaining plots of Figure 2. As with ethnic fractionalization, the reductive effect of cross-cuttingness actually decreases as ethnic bipolarization increases, though the slope is much less steep. For the two religion variables, however, the effect is exactly as specified in Hypothesis 7.1: the reductive effect of cross-cuttingness increases as each of these variables increase. In Models 6 and 7 of Table 5, for which I do not show marginal plots, the effect of cross-cuttingness continues to be negative and significant regardless of the level of the second modifying variable.⁸⁸

Next, I turn to the other single-cleavage characteristics. Since only the marginal effect of ethnic fractionalization is significant, I show only its plot in Figure 3. We see that the effect of ethnic fractionalization on civil war is significantly positive only when cross-cuttingness is high (at its mean of 0.75 or above). Thus, ethnic fractionalization increases the likelihood of civil war, as stated in Hypothesis 3.1. Contrary to this hypothesis, however, the effect of ethnic fractionalization becomes stronger as cross-cuttingness increases. Hypothesis 3.1 stated that the effect of ethnic fractionalization should weaken at higher levels of cross-cuttingness. One possible explanation of this empirical finding is that cross-cuttingness actually increases the number of preferences in society. Specifically, an additional cross-cutting cleavage may divide society into more subgroups; those subgroups then develop unique preferences for a variety of issues, making conflict more likely.

FIGURE 3 ABOUT HERE

CROSS-FRAGMENTATION AND CIVIL WAR ONSET

Next, I test whether cross-fragmentation is a significant determinant of civil war onset. As the empirics showed in the previous section, cross-fragmentation and pure cross-cuttingness are separate concepts only mildly correlated. Thus, this next section is *not* a robustness test of the concept of cross-cuttingness, but rather a test of a different characteristic of cleavage structure altogether. In contrast to pure cross-cuttingness, cross-fragmentation is not statistically significant in any of the models.⁸⁹ Nevertheless, plots of the marginal effect of cross-fragmentation (Figure 4) show similar signs and slopes to Figure 2. Similar coefficients of the other independent variables, including their signs, size and significance are also obtained in the cross-fragmentation models.

FIGURE 4 ABOUT HERE

ROBUSTNESS TO ALTERNATIVE DEFINITIONS OF CIVIL WAR

I also tested my findings using the several alternative datasets of civil war onset. These datasets included Correlates of War (COW)⁹⁰, Political Instability Task Force (PITF)⁹¹, Major Events of Political Violence (MEPV)⁹² and Fearon and Laitin (F&L)⁹³. In addition, for each of these datasets, I substituted the differing ethnic/religious fractionalization/bipolarization indices mentioned in the previous section. Here I report the results using my social structure variables.

While there are important differences in the way that these datasets define what a civil war is, I differentiate them here based on *intensity*.⁹⁴ As mentioned above, PRIO counts cases that have at least 25 annual deaths and a minimum of 1,000 conflict-related deaths during the course of the civil war. F&L has the strictest

threshold rule; it only counts cases with at least 100 annual deaths and a minimum of 1,000 deaths overall. PITF's two thresholds are at least 1000 direct conflict-related deaths over the full course of the armed conflict and at least one year when the annual conflict-related death toll exceeds 100 fatalities. COW maintains the same 1,000 overall minimum, but does not have an annual deaths minimum. MEPV has the lowest overall minimum of at least 500 directly-related deaths over the course of the episode, again with no yearly minimum. All datasets were restricted to the years 1945-1999 to maximize comparability.

TABLE 6 ABOUT HERE

Table 6 summarizes the marginal plots for cross-cuttingness using each of the three alternate datasets. Importantly, PITF, MEPV and COW yield similar results to Figure 2, confirming the robustness of the major result of this study. The F&L dataset yielded slightly different results. The two plots, described in the last two rows of Table 6, suggest that at high levels of ethnic fractionalization, cross-cuttingness actually increases the likelihood of civil war. While these results cannot be completely ignored, it is notable that the F&L dataset have the strictest intensity rules. Moreover, using other measures of ethnic fractionalization in the F&L model in Table 6 produced results in support of the major finding of this paper. Thus, we can comfortably conclude that the results are robust in all but the most intense levels of civil war. Robustness results for the other single-cleavage characteristics are not shown due to their inconsistency. Thus, the major robust finding of this paper is that the marginal effect of cross-cuttingness on civil war onset is negative and significant when ethnic fractionalization is low (less than 0.5 approximately). This result is

robust to the measure of ethnic fractionalization used, source of civil war onset data, and statistical technique.

The marginal effect of ethnic fractionalization is less certain. Two of the four alternate measures yielded insignificant results, while the other two returned similar results (including direction, range and slope) as Figure 3. Moreover, when alternate sources of civil war onset are used, the marginal effect of ethnic fractionalization is insignificant in two of the seven models (using only SELF) and in three models actually reduces the likelihood of civil war onset, though this occurs at low levels of cross-cuttingness. Lastly, in four of the models, the marginal effect of ethnic fractionalization is the same as in Figure 3. In general, then, the range and slope of Figure 3 is confirmed, but it is possible that at low levels of cross-cuttingness, ethnic fractionalization actually reduces the likelihood of civil war. In the conclusion, I address future strategies to assess these results further.

ROBUSTNESS TO ETHNIC CIVIL WARS

There is some disagreement in the literature regarding the use of general civil wars vs. ethnic civil wars as the dependent variable. Proponents of using the latter argue that ethnic wars have different determinants than other types of civil war.⁹⁵ As such, I ran all the models using three different sources for ethnic civil wars onset data: Major Events of Political Violence (MEPV), Fearon and Laitin (F&L), and Political Instability Task Force (PITF), the latter of which I coded myself for ethnic wars. The major results of this paper are supported substituting in measures of ethnic civil wars. The marginal effect of cross-cuttingness is significant in all three models, while the marginal effect of ethnic fragmentation is significant in two of the three regressions.⁹⁶

CONCLUSION

I started by arguing that past models of civil war onset seeking to test the influence of social structure are biased because they do not consider the structure of cleavages. Indeed, this study has confirmed that when single-cleavage social structure characteristics are regressed on civil war they are insignificant. While intuition tells us that social structure should matter, the vast number of past studies have been inconclusive. This paper has suggested that characteristics capturing how two (or more) cleavages are structurally related to each other are an important part of measuring social structure. The empirical results have shown that one such characteristic, cross-cuttingness, is a significant determinant of civil war onset at low levels of ethnic fractionalization. However, the empirical evidence for cross-fragmentation is not so favourable. Moreover, there is weaker support for the marginal effect of ethnic fractionalization, and even weaker evidence that any of the single-cleavage characteristics significantly determine civil war.

Yet, this study is only the beginning of a more comprehensive approach to both conceptualizing and measuring social structure. Two other important characteristics come to mind. First, the geographic dispersion of ethnic and religious groups may be important for the actual physical interaction of groups. Consider two highly cross-cutting societies where two ethnic groups share a single religion. In one country, however, ethnic groups are evenly dispersed around the country, whereas in the other they are concentrated in certain regions. In the first society, the ethno-religious cross-cuttingness is more likely to result in actual physical interaction between ethnic groups, but not in the latter. Ethnic groups living near each other might go to the same churches, mosques or temples, or be involved in intra-ethnic organizations or events. In the second country, shared religious identity may not mean much at all. One way to capture this is the ever elusive measure of which cleavages are salient. However, a measure more achievable in the near future might be

a geographic segregation measure similarly derived from surveys.⁹⁷ A second characteristic to be included in future studies should be something that captures the economic inequality among ethnic (or religious) groups. While we might think that ethnic and religious disputes transcend economic “greed”, wealth disparity should intensify ascriptive differences. Again, national surveys provide a ready source for such data.

In conclusion, we currently have very little understanding about if and how social structure might affect the likelihood of social conflict. Ethno-religious cross-cuttingness is one step toward a richer sociological theory, and has been shown in this study to be a significant determinant of civil war onset. Certainly any future study should include cross-cuttingness in a multiplicative specification.

- ¹⁵ *ibid.*

¹⁶ I use the broader term *social structure* to refer to a description of macro social cleavages and groups including characteristics of individual cleavages and/or groups as well as the relationship of cleavages to each other.

¹⁷ A cleavage is a “division on the basis of some criteria of individuals, groups, or organizations [between] whom conflict may arise” (Lane and Ersson 1994).

¹⁸ Donald L. Horowitz, *Ethnic Groups in Conflict* (Berkeley: University of California Press, 1985).

²¹ In other work, I use a cross-cutting index of ethnicity and income to try and measure this. See: Joel Selway and Joshua Gubler, "Ethno-Income Inequality, Ethno-Geographic Dispersion, Ethno-Religious Cross-Cuttingness and Civil War Onset," *Under Review* (2008).

²² Cederman, Lars-Erik, Jan Ketil Rød, and Nils Weidmann. "Geo-Referencing of Ethnic Groups: Creating a New Dataset".

²³ All the previously cited cleavages have been or can be further dissected: ethnicity into race and language, religion into sects and denominations, and geography into region, rural-urban residence, and center-periphery.

²⁴ I explicitly separate the two cleavages as distinct, while recognizing that much recent work on ethnicity incorporates religion into a broader definition of ethnicity. See: A. Varshney, *Ethnic Conflict and Civic Life*, (New Haven, CT: Yale Univ. Press 2002); Chandra K., *Why Ethnic Parties Succeed*. Cambridge, (UK: Cambridge Univ. Press 2004); Daniel N. Posner, "Measuring Ethnic Fractionalization in Africa," *American Journal of Political Science* 48 (2004), 849-863. This decision comes with tradeoffs, most important of which is that in countries where ethnicity and religion seem virtually inseparable, such as Malaysia, we cannot know whether a measure of cross-cuttingness is meaningful. More broadly, we can categorize this in the long-standing challenge of measuring the salience of cleavages in society.

²⁵ Douglas W. Rae and Michael Taylor, *The Analysis of Political Cleavages*.

²⁶ Donald L. Horowitz, *Ethnic Groups in Conflict*; Jonathan Fox, *Religion, Civilization, and Civil War*:

²⁷ There is a growing sociological literature, under the rubric of the “religious economy”, which argues that switching religions (especially denominations within religions) is more common than many think. In my dataset, for most of the countries that appeared in more than one survey over time, there appeared to be minimal changes in the scores. On the whole this supports my assertion that religious and ethnic identity are difficult, though not impossible, to change, especially when they are the bases for conflict.

²⁸ A group is a category of identity/membership within a single cleavage, such as Christian and Muslim within the religion cleavage.

³¹ Daniel N. Posner, "Measuring Ethnic Fractionalization in Africa", p. 853.

³² Easterly and Levine, for example, use the terms *ethnic diversity*, *polarization*, and *ethnic fractionalization* almost interchangeably in their path-breaking study on how ethnicity affects economic growth. See: W. Easterly and R. Levine, "Africa's Growth Tragedy: Policies and Ethnic Divisions," *Quarterly Journal of Economics* 112 (1997), 1203-1250.

³³ Scholars have used some variation of the Herfindahl index of fractionalization to measure the effective number of ethnic or religious groups in a society. Specifically, $F = \sum_{i=1}^N p_i (1 - p_i)$, where p_i is the proportion of society that identifies with a given ethnic group.

³⁴ M. Reynal-Querol, "Ethnicity, Political Systems, and Civil Wars," *Journal of Conflict Resolution* 46 (2002), 29-54. Reynal-Querol actually uses the term *polarization*, which has often been used in the Political Science literature to describe the cultural distance between groups on a given cleavage. She

uses the equation $R = \sum_{i=1}^N p_i^2 \frac{(0.5 - p_i)^2}{0.5}$, where p_i is again the proportion of society that identifies with a given ethnic group. While this equation is similar to Esteban and Ray's measure of polarization,

Reynal-Querol imposes an assumption that the distance, or intensity of difference, between any pair of groups is identical. In other words, cultural distance is already contained in the underlying assumption. To avoid confusion with cultural polarization, I use the term *bipolarization*, since the measure is maximized with two groups (or two poles) of equal size. See: J. M. Esteban and D. Ray, "On the Measurement of Polarization," *Econometrica* 62 (1994), 819-851.

⁴¹ Paul Collier and Anke Hoefler, "Greed and Grievance in Civil War". Annett also offers a measure of social fractionalization, which captures fractionalization on both the religious and ethnic cleavages - defined as one half times the value of ethnic fractionalization plus one half times the value of religious fractionalization. To date, I have not seen this measure used in a study of civil war. See: Anthony Annett, "Social Fractionalization, Political Instability, and the Size of Government," *IMF Staff papers* Vol. 48 (2001).

⁴² David Frisby and Gerd Schroeter, "George Simmel // Review," *The Canadian Review of Sociology and Anthropology* 23 (1986), p. 285.

⁴³ This term is my own. Past references to this same characteristic/phenomenon include cross-cutting cleavages, cross-cutting circles, criss-cross pattern of cleavage structure, intersection of cleavages. The antonym (reinforcing) has also been referred to as overlapping cleavages, consolidation of cleavages, superimposition of lines of differentiation, correspondence of cleavages.

⁵⁴ Douglas W. Rae and Michael Taylor, *The Analysis of Political Cleavages* (New Haven: Yale University Press, 1970).

⁵⁵ In between the individual and cleavage levels of analysis is the group-level dynamic. Cross-fragmentation, furthermore, dissolves in-groups and diminishes group pressures. To motivate measures of cross-cuttingness, I thus pose the question: "In what way should groups on a cleavage x be distributed amongst groups on a second cleavage y to maximize cross-cuttingness?" This question motivates at least two additional measures—*cross-proportionalization* and *cross-bipolarization*—and indeed is able to motivate our first two measures also. Indices for these measures have not yet been computed, but are forthcoming. See: Joel Selway, "Cross-cutting Cleavages: Theory and Measurement of Social Structure".

⁵⁷ Seymour Martin Lipset, *Political Man; the Social Bases of Politics*.

⁵⁸ Douglas W. Rae and Michael Taylor, *The Analysis of Political Cleavages*.

⁵⁹ Since the statistics literature is unclear on which measure is superior, I opt for the more widely used Cramer's V . See: Alan Agresti, *Categorical Data Analysis* (New York: Wiley-Interscience, 2002).

⁶⁰ O stands for the observed frequencies in a simple cross-tabulation of the religious and ethnic

cleavages. E stands for expected frequencies, calculated by multiplying the two marginal frequencies from the original cross-tabulation. i refers to cells in the contingency table.

⁶¹ However, neither heterogeneity nor sub-group fractionalization are sensitive to group identity on both cleavages, and thus do not capture cross-cuttingness. A simple example illustrates why sub-group fractionalization is not a measure of cross-cuttingness. Consider Society A with its two ethnic groups, black and white, each composing 50% of the population, and its two religions, Christian and Muslim, each also composing 50% of the population. The sub-group fractionalization score for Society A is 0.5. In a second society, B, we could have a society with the same sub-group fractionalization score, 0.5, but with a huge difference in the structure of its cleavages. Specifically, in Society B there is just one ethnic group split 50-50 amongst religions. We can thus see where subgroup fractionalization fails to capture the concept of cross-cuttingness: it is not sensitive to the identities of the groups that compose the subgroups. Selway identifies this as a cross-cuttingness axiom. See: Joel Selway, "Cross-cutting Cleavages: Theory and Measurement of Social Structure," *Under Review* (2007).

⁶² Collier and Hoeffler imply this relationship should be interactive also. See: Paul Collier and Anke Hoeffler, "Greed and Grievance in Civil War," p.570.

⁷⁰ Appendix available at author's website, <http://www.umich.edu/~jselway>

⁷¹ See author's website <http://www.umich.edu/~jselway>.

⁷² The raw data, including tables from these analyses will eventually be available at the author's website <http://www.umich.edu/~jselway>.

⁷³ This comparison was necessarily restricted to African countries, and thus the Afrobarometer and World Values Survey, since Posner's index concentrates on Africa. The results are, nevertheless, encouraging. See: Daniel N. Posner, "Measuring Ethnic Fractionalization in Africa". Full analysis available in the appendix at <http://www.umich.edu/~jselway>.

⁷⁴ There may be additional problems of representativeness in terms of the self-selection bias inherent in the types of surveys I am using. While this may exclude countries that have recently experienced civil war, the data go back far enough to diminish this problem.

⁷⁵ IMF, "World Economic Outlook Database," International Monetary Fund, (2007).

⁷⁶ J. D. Fearon and D. D. Laitin, "Ethnicity, Insurgency, and Civil War".

⁷⁷ See: Nathaniel Beck, Jonathan N. Katz and Richard Tucker, "Taking Time Seriously: Time-Series-Cross-Section Analysis with a Binary Dependent Variable," *American Journal of Political Science* 42 (1998), 1260-1288. I also experiment with two alternative ways to control for time dependence. First, I use a lagged variable for the occurrence of war as Fearon and Laitin do. See: J. D. Fearon and D. D. Laitin, "Ethnicity, Insurgency, and Civil War". Additionally, I follow Hegre et al.'s method of using a

variable that assumes that the effect of a previous conflict is decaying over time according to the formula $\exp\{(-\text{peace years})/X\}$, where ‘peace years’ is the number of years since a country experienced a civil war. See: H. Hegre and N. Sambanis, "Sensitivity Analysis of Empirical Results on Civil War Onset". The value X determines the rate of decay. I follow Tose et al. and set X to 4, implying that the risk of civil war is halved approximately every 3 years. See: H. P. W. Tose, N. P. Gleditsch and H. Hegre, "Shared Rivers and Interstate Conflict," *Political Geography* 19 (2000), 971-996. This decaying variable takes on values close to 1 immediately after the end of a conflict and approaches 0 over time. The major results are not appreciably affected by these various approaches.

⁷⁸ N. P. Gleditsch, P. Wallensteen, M. Eriksson, M. Sollenberg and H. Strand, "Armed Conflict 1946-2001: A New Dataset," *Journal of Peace Research* 39 (2002), 615-637. Sometimes referred to as the “Armed Conflict Data”, the PRIO data I use were restricted to conflicts with at least 1000 battle deaths by Urdal. I thank him for his generous sharing of data. See: Henrik Urdal, "A Clash of Generations? Youth Bulges and Political Violence," *International Studies Quarterly* 50 (2006), 607-629.

⁷⁹ Appendix available at <http://www.umich.edu/~jselway>

⁸⁰ Paul Collier and Anke Hoeffler, "Greed and Grievance in Civil War," *Oxford Economic Papers* 56 (2004).

⁸¹ Paul Collier and Anke Hoeffler, "Greed and Grievance in Civil War".

⁸² The exact definition is a country with territory holding at least 10,000 people and separated from the land area containing the capital city either by land or by 100 kilometers of water were coded as “noncontiguous.” See: J. D. Fearon and D. D. Laitin, "Ethnicity, Insurgency, and Civil War".

⁸³ I also include a measure of democracy based on the Polity IV index, which ranges from 10, most democratic, to -10, least democratic (*Democracy*). All these variables are taken from Fearon and Laitin. I thank them for their generous sharing of data. See: J. D. Fearon and D. D. Laitin, "Ethnicity, Insurgency, and Civil War".

⁸⁴ Coefficients on each of the single-dimension characteristics were also statistically insignificant, as were various combinations of pairs of these variables. For the sake of space, these results are not displayed.

⁸⁵ In addition, I ran models using all the other indices of civil war used in this paper and all other social structure variables. The conclusion is that F&L’s results on *Oil* and *Income* are not robust.

⁸⁶ I note that I also find mixed results for ethnic and religious bipolarization measures, which Montalvo and Reynal-Querol show strong empirical support for. See: J. G. Montalvo and M. Reynal-Querol,

"Ethnic Polarization, Potential Conflict, and Civil Wars".
